

**Exercise 7: Strain****06.12.2021 - 10.12.2021****Question 1** .....

Consider the following displacement field,

$$\mathbf{u}(x, y, z) = k \begin{bmatrix} 2x + y^2 \\ x^2 - 3y^2 \\ 0 \end{bmatrix},$$

where  $k$  is a nonzero constant. Calculate the strain tensor  $\varepsilon$ !**Solution:** The strain tensor  $\varepsilon$  was defined in the lecture by

$$\varepsilon = \frac{1}{2} \left( \vec{\nabla} \vec{u} + (\vec{\nabla} \vec{u})^T \right) \quad \text{or in index notation} \quad \varepsilon_{ij} = \frac{1}{2} \left( \frac{\partial u_i}{\partial r_j} + \frac{\partial u_j}{\partial r_i} \right)$$

With this formulas you are able to compute each component of the strain tensor

$$\begin{aligned} \varepsilon_{xx} &= \frac{1}{2} \left( \frac{\partial u_x}{\partial x} + \frac{\partial u_x}{\partial x} \right) = \frac{\partial(2x + y^2)}{\partial x} = 2k \\ \varepsilon_{xy} &= \frac{1}{2} \left( \frac{\partial u_x}{\partial y} + \frac{\partial u_y}{\partial x} \right) = \frac{1}{2} \left( \frac{\partial(2x + y^2)}{\partial y} + \frac{\partial(x^2 - 3y^2)}{\partial x} \right) = \frac{1}{2} (2ky + 2kx) = k(x + y) \\ \varepsilon_{yy} &= \frac{1}{2} \left( \frac{\partial u_y}{\partial y} + \frac{\partial u_y}{\partial y} \right) = \frac{\partial(x^2 - 3y^2)}{\partial y} = -6ky \\ &\dots \end{aligned}$$

By using the symmetry of  $\varepsilon$  you only have to compute 6 entries and should find the following result

$$\varepsilon = k \begin{bmatrix} 2 & x + y & 0 \\ x + y & -6y & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

Note that all components of  $\varepsilon$  involving the  $z$ -direction are zero. This situation is called *plane strain*.**Question 2** .....A solid bar with dimensions  $l \times w \times w$  (see below) is stretched along its length to a final length  $al$ . The volume of the bar does not change during deformation. Calculate the displacement vector  $\mathbf{u}$  and the strain tensor  $\varepsilon$ !

**Solution:** After stretching, the bar has a new width  $\hat{w}$ . However, the volume is conserved, therefore

$$\hat{w}^2 l a = w^2 l \implies \hat{w} = \frac{w}{\sqrt{a}}.$$

We assume the bar deforms homogeneously. The displacement along the  $x$ -direction increases linearly from zero at  $x = 0$  to  $(a - 1)l$  at  $x = l$ . Similarly, the displacement in  $y$ -direction increases linearly from zero at  $y = 0$  to some maximum value at  $y = w/2$ . The displacement in  $z$ -direction increases linearly from zero at  $z = 0$  to some maximum value at  $z = w/2$ . The bar retains its square cross-section, i.e. the  $y$ -displacement does not depend on  $x$  and  $z$ , and the  $z$ -displacement does not depend on  $y$  and  $x$ . Therefore, the displacement vector can be written as

$$\mathbf{u} = \begin{bmatrix} (a - 1)x \\ Ay + B \\ Cz + D \end{bmatrix},$$

where  $A, B, C, D$  are constants that need to be determined by consideration of the boundary conditions. Since the  $y$ - and  $z$ - components are zero at  $y = 0$  and  $z = 0$ , respectively, we see that  $B = D = 0$ . The bar retains its square cross-section, i.e. the  $y$ -displacement at  $y = w/2$  must be equal to the  $z$ -displacement at  $z = w/2$ . Therefore  $A = C$ . Recall that the new width after deformation is  $\hat{w} = w/\sqrt{a}$ . For this reason, the  $y$ -displacement at  $y = w/2$  must be equal to  $(\hat{w} - w)/2 = (1/\sqrt{a} - 1)w/2$ . It must also be equal to  $Aw/2$ . Therefore  $A = (1/\sqrt{a} - 1)$ . In conclusion, the displacement vector is

$$\mathbf{u} = \begin{bmatrix} (a - 1)x \\ \left(\frac{1}{\sqrt{a}} - 1\right)y \\ \left(\frac{1}{\sqrt{a}} - 1\right)z \end{bmatrix}.$$

Through differentiation, we obtain the strain tensor

$$\varepsilon = \begin{bmatrix} a - 1 & 0 & 0 \\ 0 & \frac{1}{\sqrt{a}} - 1 & 0 \\ 0 & 0 & \frac{1}{\sqrt{a}} - 1 \end{bmatrix}.$$

**Question 3** .....  
(Saint-Venant's compatibility conditions)

The strain tensor  $\varepsilon$  has six distinct components. However, these six components are computed from only three components of the displacement vector  $\mathbf{u}$ . Thus, if we want to solve for the components of  $\mathbf{u}$  given the component of  $\varepsilon$ , we have six equations for three unknowns. For this system of equations to have a solution, some of the strain components must be related. Show that they are by considering their second derivatives! For example, differentiate  $\varepsilon_{xx}$  twice with respect to  $y$ ,  $\varepsilon_{yy}$  twice with respect to  $x$  and  $\varepsilon_{xy}$  with respect to  $x$  and  $y$ , and compare!

**Solution:** Recall the definition of the aforementioned strain components,

$$\begin{aligned} \varepsilon_{xx} &= \frac{\partial u_x}{\partial x}, \\ \varepsilon_{yy} &= \frac{\partial u_y}{\partial y}, \\ \varepsilon_{xy} &= \frac{1}{2} \left( \frac{\partial u_x}{\partial y} + \frac{\partial u_y}{\partial x} \right). \end{aligned}$$

Thus,

$$\begin{aligned}\frac{\partial^2 \varepsilon_{xx}}{\partial y^2} &= \frac{\partial^3 u_x}{\partial x \partial y^2}, \\ \frac{\partial^2 \varepsilon_{yy}}{\partial x^2} &= \frac{\partial^3 u_y}{\partial y \partial x^2},\end{aligned}$$

and

$$\begin{aligned}\frac{\partial^2 \varepsilon_{xy}}{\partial x \partial y} &= \frac{1}{2} \frac{\partial^2}{\partial x \partial y} \left( \frac{\partial u_x}{\partial y} + \frac{\partial u_y}{\partial x} \right), \\ &= \frac{1}{2} \left( \frac{\partial^3 u_x}{\partial y^2 \partial x} + \frac{\partial^3 u_y}{\partial x^2 \partial y} \right).\end{aligned}$$

The order of differentiation in the last equation is immaterial, hence we see that

$$\frac{\partial^2 \varepsilon_{xx}}{\partial y^2} + \frac{\partial^2 \varepsilon_{yy}}{\partial x^2} = 2 \frac{\partial^2 \varepsilon_{xy}}{\partial x \partial y}.$$

Two more equations of this form can be obtained by repeating this procedure for  $\varepsilon_{yy}$ ,  $\varepsilon_{zz}$ , and  $\varepsilon_{yz}$ , and for  $\varepsilon_{xx}$ ,  $\varepsilon_{zz}$ , and  $\varepsilon_{xz}$ . This is tantamount to cyclic permutations of the indices,  $x \rightarrow y$ ,  $y \rightarrow z$ , and  $z \rightarrow x$ .

Three more equations can be obtained by considering mixed derivatives of type

$$\frac{\partial^2 \varepsilon_{xx}}{\partial y \partial z} = \frac{\partial^3 u_x}{\partial x \partial y \partial z}.$$

Again, order of differentiation is immaterial, hence

$$\begin{aligned}\frac{\partial^3 u_x}{\partial x \partial y \partial z} &= \frac{\partial^2}{\partial x \partial z} \left( \frac{\partial u_x}{\partial y} \right) \\ &= \frac{\partial^2}{\partial x \partial z} \left( 2\varepsilon_{xy} - \frac{\partial u_y}{\partial x} \right) \\ &= \frac{\partial}{\partial x} \left( 2 \frac{\partial \varepsilon_{xy}}{\partial z} - \frac{\partial^2 u_y}{\partial x \partial z} \right).\end{aligned}$$

Similarly,

$$\begin{aligned}\frac{\partial^3 u_x}{\partial x \partial y \partial z} &= \frac{\partial^2}{\partial x \partial y} \left( \frac{\partial u_x}{\partial z} \right) \\ &= \frac{\partial^2}{\partial x \partial y} \left( 2\varepsilon_{xz} - \frac{\partial u_z}{\partial x} \right) \\ &= \frac{\partial}{\partial x} \left( 2 \frac{\partial \varepsilon_{xz}}{\partial y} - \frac{\partial^2 u_z}{\partial x \partial y} \right).\end{aligned}$$

Combining gives

$$\begin{aligned}2 \frac{\partial^3 u_x}{\partial x \partial y \partial z} &= \frac{\partial}{\partial x} \left( 2 \frac{\partial \varepsilon_{xy}}{\partial z} - \frac{\partial^2 u_y}{\partial x \partial z} \right) + \frac{\partial}{\partial x} \left( 2 \frac{\partial \varepsilon_{xz}}{\partial y} - \frac{\partial^2 u_z}{\partial x \partial y} \right) \\ &= \frac{\partial}{\partial x} \left( 2 \frac{\partial \varepsilon_{xy}}{\partial z} + 2 \frac{\partial \varepsilon_{xz}}{\partial y} - \frac{\partial u_y}{\partial z} - \frac{\partial u_z}{\partial y} \right) \\ &= 2 \frac{\partial}{\partial x} \left( \frac{\partial \varepsilon_{xy}}{\partial z} + \frac{\partial \varepsilon_{xz}}{\partial y} - \frac{\partial \varepsilon_{yz}}{\partial x} \right).\end{aligned}$$

Finally,

$$\frac{\partial^2 \varepsilon_{xx}}{\partial y \partial z} = \frac{\partial}{\partial x} \left( \frac{\partial \varepsilon_{xy}}{\partial z} + \frac{\partial \varepsilon_{xz}}{\partial y} - \frac{\partial \varepsilon_{yz}}{\partial x} \right)$$

The other two equations of this type can be obtained by cyclic permutation of the indices,  $x \rightarrow y$ ,  $y \rightarrow z$ , and  $z \rightarrow x$ . The six compatibility conditions are therefore

$$2 \frac{\partial^2 \varepsilon_{xy}}{\partial x \partial y} = \frac{\partial^2 \varepsilon_{xx}}{\partial y^2} + \frac{\partial^2 \varepsilon_{yy}}{\partial x^2} \quad (\text{a}),$$

$$2 \frac{\partial^2 \varepsilon_{yz}}{\partial y \partial z} = \frac{\partial^2 \varepsilon_{yy}}{\partial z^2} + \frac{\partial^2 \varepsilon_{zz}}{\partial y^2} \quad (\text{b}),$$

$$2 \frac{\partial^2 \varepsilon_{zx}}{\partial z \partial x} = \frac{\partial^2 \varepsilon_{zz}}{\partial x^2} + \frac{\partial^2 \varepsilon_{xx}}{\partial z^2} \quad (\text{c}),$$

$$\frac{\partial^2 \varepsilon_{xx}}{\partial y \partial z} = \frac{\partial}{\partial x} \left( \frac{\partial \varepsilon_{xy}}{\partial z} + \frac{\partial \varepsilon_{xz}}{\partial y} - \frac{\partial \varepsilon_{yz}}{\partial x} \right) \quad (\text{d}),$$

$$\frac{\partial^2 \varepsilon_{yy}}{\partial z \partial x} = \frac{\partial}{\partial y} \left( \frac{\partial \varepsilon_{yz}}{\partial x} + \frac{\partial \varepsilon_{yx}}{\partial z} - \frac{\partial \varepsilon_{zx}}{\partial y} \right) \quad (\text{e}),$$

$$\frac{\partial^2 \varepsilon_{zz}}{\partial x \partial y} = \frac{\partial}{\partial z} \left( \frac{\partial \varepsilon_{zx}}{\partial y} + \frac{\partial \varepsilon_{zy}}{\partial x} - \frac{\partial \varepsilon_{xy}}{\partial z} \right) \quad (\text{f}).$$

#### Question 4 .....

In the first question, you computed the strain tensor  $\varepsilon$  for displacement field

$$\mathbf{u}(x, y, z) = k \begin{bmatrix} 2x + y^2 \\ x^2 - 3y^2 \\ 0 \end{bmatrix}.$$

Now show that  $\varepsilon$  fulfills the compatibility conditions!

**Solution:** Recall that

$$\varepsilon = \begin{bmatrix} 2 & x + y & 0 \\ x + y & 2x & 0 \\ 0 & 0 & 0 \end{bmatrix}.$$

Note that all components of  $\varepsilon$  involving the  $z$ -direction are zero (*plane strain*). All derivatives with respect to  $z$  are zero. Moreover,  $\varepsilon$  is linear in  $x$  and  $y$ . Therefore, all terms of the type  $\partial^2(\dots)/\partial x^2$  and  $\partial^2(\dots)/\partial y^2$  are zero. The only non zero term that is left over is  $\frac{\partial^2 \varepsilon_{xy}}{\partial x \partial y}$ . We can inspect this term in the first condition (a)

$$\begin{aligned} 2 \frac{\partial^2 \varepsilon_{xy}}{\partial x \partial y} &= 0 + 0 \\ \Leftrightarrow 2 \frac{\partial}{\partial y} \left( \frac{\partial \varepsilon_{xy}}{\partial x} \right) &= 0 \\ \Leftrightarrow 2 \frac{\partial}{\partial y} (1) &= 0 \\ \Leftrightarrow 0 &= 0 \quad \text{OK!} \end{aligned}$$

so the derivative  $\frac{\partial^2 \varepsilon_{xy}}{\partial x \partial y} = 0$ . Thus, we can immediately see that conditions (b)–(f) are fulfilled. Therefore the strains are compatible.
